

Adjustable Thermostats for Power Attic Ventilators

The Adjustable Thermostat included with the above Models of Power Attic Ventilators is designed to turn the fan on and off automatically.

THERMOSTAT SETTING

The thermostat setting governs the "fan off" temperature, i.e., the temperature at which the fan turns OFF. When the temperature rises 15° above the "fan off" temperature, the fan turns ON. As the temperature in the attic is reduced, the fan turns off when the temperature in the attic reaches the "fan off" thermostat setting.

The adjustable thermostat is pre-set at the factory at 90°. This setting is user-adjustable. The setting that is best for your attic varies by geographical location.

A setting that is too low will cause the fan to run constantly; a setting that is too high will cause the attic to be over-heated since the fan will not turn on until the temperature rises 15° above the "fan off" thermostat setting.

CONTROLLING MULTIPLE VENTILATORS

The thermostat can control multiple Power Attic Ventilators (up to 3) or a single unit not to exceed 15 amps, 120 volts AC.

IMPORTANT: When using multiple ventilators in a single installation, be sure that all ventilators are wired to the same thermostat so that the ventilators operate simultaneously. This will prevent a ventilator from pulling heat into the attic from a second ventilator.

INSTALLATION

The thermostat should be installed in such a way that the thermostat sensor, which is on the back of the control box, is not blocked. Usually, it is best to choose a location where the control box can be suspended from one of the rafters.

IMPORTANT! THE THERMOSTAT COVER MUST BE REMOVED IN ORDER TO PROPERLY WIRE THE THERMOSTAT. Failure to wire the thermostat according to the diagram below will circumvent the thermostat entirely, and the fan will not turn off.

If using the thermostat to control multiple ventilators in the same installation, see note above regarding Multiple Ventilators.
